

10 of 10 settings favour DISEIL. Setting level ($n = 10$): sign test and Wilcoxon, two-sided $p = 0.002$ — the floor for 10 pairs.
Task level ($n = 5$, which absorbs the correlation between the two modalities of a task): 5/5, paired $t(4) = 4.15$, $p = 0.014$.
The conservative task-level result is the one to lead with. Bars are the standard error of the paired difference; they are not the test.
Lift is at the 100.0 ± 0.0 ceiling and is uninformative about any mechanism.
